Identifying low vigor trees...what makes a sick tree look sick..

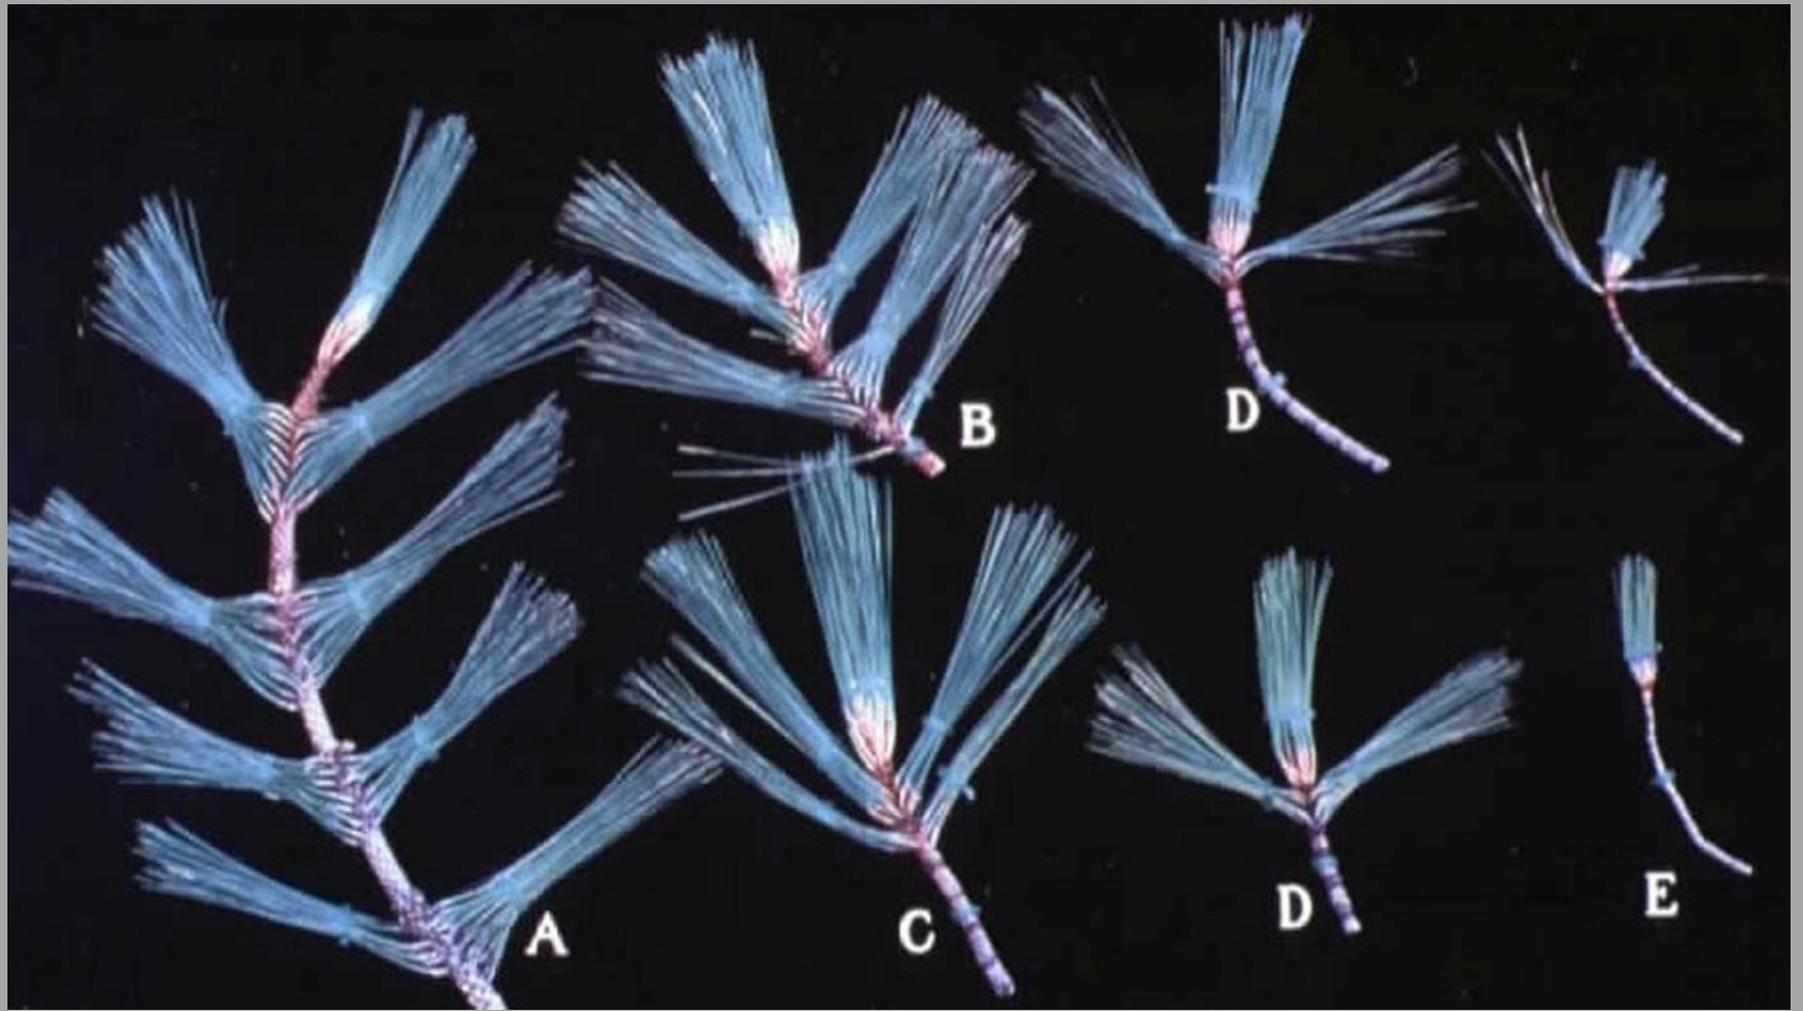

Chlorosis

Loss of older needle age classes

1) Establish relationship between qualitative vigor assessments and quantitative measurements:

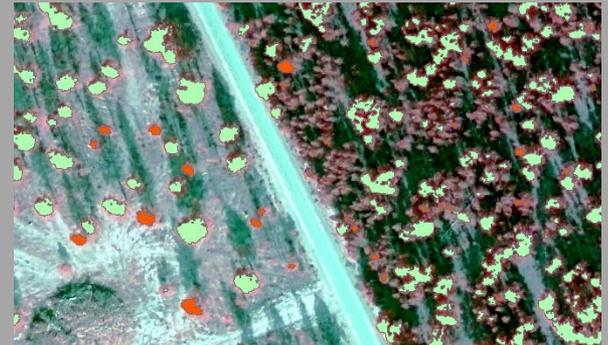

- Are the trees that look poor have the data behind them?
- Yes, statistical significance for chlorosis, # of whorls, branch diameter, dwarf mistletoe for trees qualitatively ranked as 'good', 'fair', 'poor'

2) Establish relationship between qualitative vigor assessments and crown spectral data from imagery:

- Are the trees that look poor have the data behind them?
- Yes, statistical significance for NDVI, NIR, GCC, DVI (spectral indices) for trees qualitatively ranked in two classes: as 'poor' and 'not poor'

Image processing/modeling

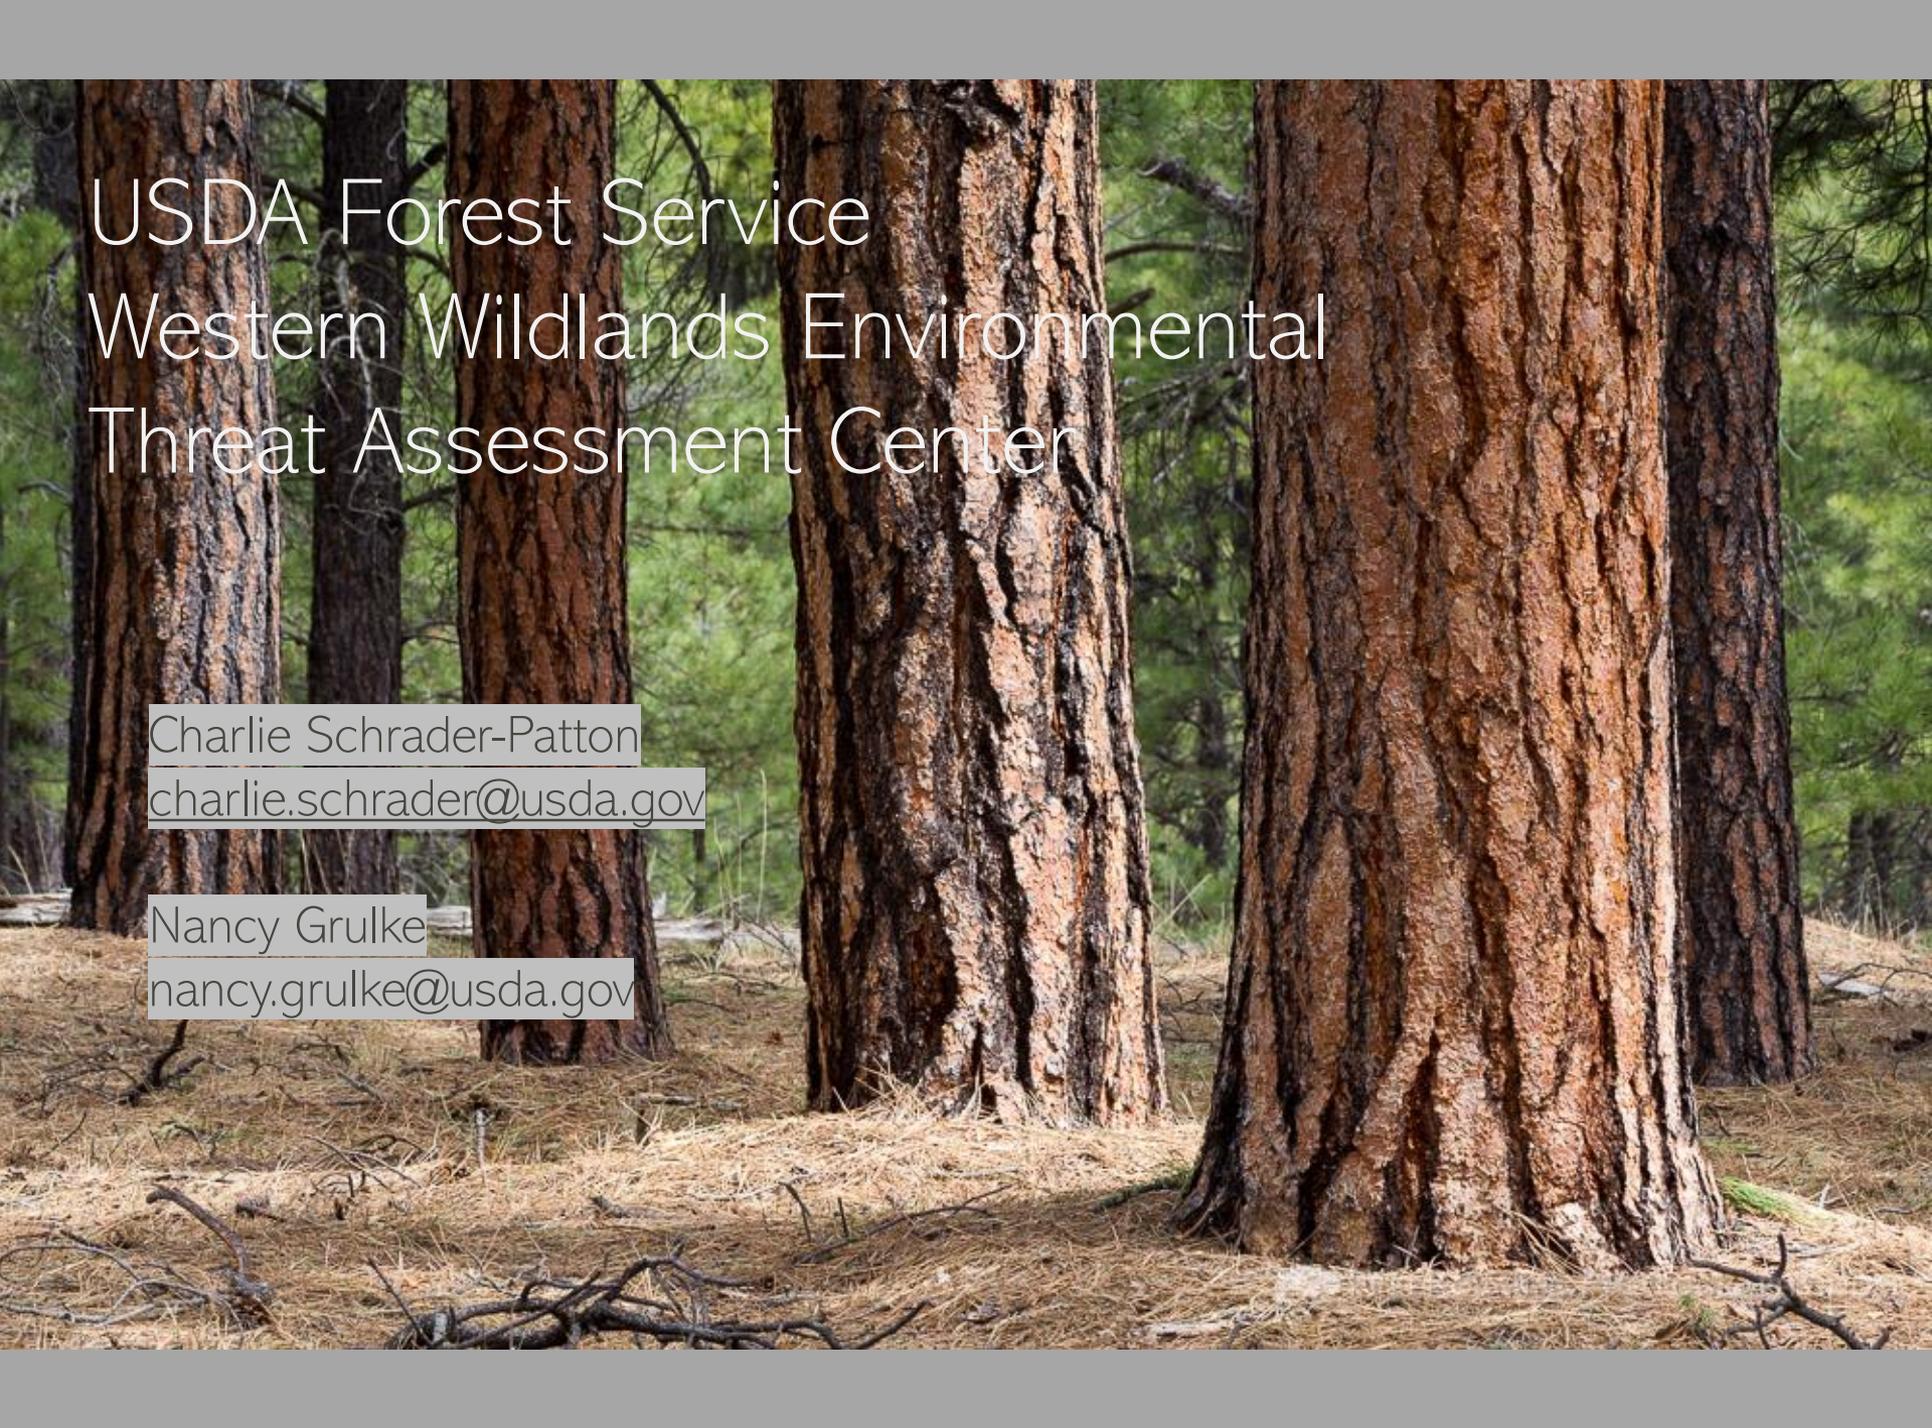

- 4-Band, 30cm aerial imagery
 - Red, Green, Blue, Near-Infrared
- Tree crowns as objects
- Random Forests machine learning
 - Predictors – 11 spectral derivatives
 - NDVI, EVI, GCC, RCC, R, G, B, NIR
- 3 different silvicultural prescriptions, plus control

Results

- 77% accuracy in mapping
 - two classes of trees:
 - poor and not poor.
- Treatments
 - Stands burned and thinned I highest vigor.
 - Even thinning – higher vigor than patchy thinning.
 - Stands burned twice (2006 and 2013) were higher in vigor than those burned once (2008)
