COMPOST FLOW CHART

Moisture & Aeration
All life on Earth needs a certain amount of water and air to sustain itself. The microbes in the compost need water and heat to break down the organic matter. The moisture and aeration of the compost pile are critical.

Time & Temperature
The composting process generates heat. The faster the composting, the hotter the pile. Piles that are too dry or too moist can inhibit the composting process. The ideal temperature for composting is generally between 130°F and 150°F.

Surface Area
The surface area of the compost pile is important. A pile that is too large may not get the necessary heat to break down the organic matter. Piles smaller than 3 feet cubed (27 cu.ft.) usually reach the necessary temperature and nutrients are released to the soil.

Adequate composting will hold this heat, while piles that are too small or not properly managed may not hold the heat. Piles less than 3 feet cubed (27 cu.ft.) may not get the necessary heat to break down the organic matter.

What Can I Compost?
Compost is made from materials that were once alive. Anything that was once alive can be composted. This includes yard wastes, food scraps, and other organic materials.

Why should I make compost?
Composting is the most practical and convenient way to handle your organic wastes. It reduces the amount of trash going into landfills and helps reduce greenhouse gas emissions. Composting also improves the health of your soil and plants.

Other Resources
- Materials for Home Composting (supplemental SCRSWS brochure on C:N Ratios), 2014
- Clean Green programs for foods/recyclables - contact your garbage hauler
- Worms Eat My Garbage by Mary Appelhof, Flowerfield Enterprises, LLC, 1997

Home Composting
What is Compost?
It is a dark, crumbly, and earthy-smelling form of decomposing organic matter.

The Essentials of Composting
- Materials: yard wastes, food scraps, and other organic materials
- Methods: piling, turning, and heating
- Benefits: reduces trash, improves soil, and conserves resources

With these principles in mind, everyone can make excellent use of their organic wastes.

Spokane County Master Composter/Recycler Program
2900 S. Geiger Blvd, Spokane, WA 99224
The Master Composter/Recycler Program is sponsored by the Spokane County Regional Solid Waste System. Master Composters/ Recyclers are volunteers who are working to promote the practice of home composting throughout Spokane County.

Recycling Hot Line 477-6800

Printed on recycled/recyclable paper with partial funding from a grant from WA State Department of Ecology.
The Essentials of Composting

With these principles in mind, everyone can make excellent use of their organic wastes.

**Biology**

The compost pile is really a teeming microbial farm. Bacteria start the process of decaying organic matter. They are the first to break down plant tissue and also the most numerous and effective composters. Fungi and protozoans soon join the bacteria and, somewhat later in the cycle, composting microorganisms, millipedes, beetles and earthworms do their parts.

**Materials**

Anything growing in your yard is potential food for these tiny decomposers. Carbon and nitrogen from the cells of dead plants and dead microbes fuel their activity. The micro-organisms use the carbon in leaves or woodier wastes as an energy source. Nitrogen provides the microbes with the raw element of proteins to build their bodies.

Everything organic has a ratio of carbon to nitrogen (C:N) in its tissues, ranging form 500:1 for sawdust, to 25:1 for table scraps. A C:N ratio of 30:1 is ideal for the activity of compost microbes. This balance can be achieved by mixing two parts grass clippings (which have a C:N ratio of 20:1) with one part fallen leaves (60:1). Layering can be useful in arriving at these proportions, but a complete mixing of ingredients is preferable for the composting process. Other materials can also be used, such as garden wastes. Though the C:N ratio of 30:1 is ideal for a fast, hot compost, a higher ratio (i.e., 50:1) will be adequate for a slower compost.

**Surface Area**

The more surface area the microorganisms have to work on, the faster the materials are decomposed. It’s like a block of ice in the sun—slow to melt when it is large, but melting very fast when broken into smaller pieces. Chopping your garden wastes with a shovel or machete, or running them through a shredding machine or lawn mower will speed their composting.

**Volume**

A large compost pile will insulate itself and hold the heat of microbial activity. Its center will be warmer than its edges. Piles smaller than 3 feet cubed (27 cu.ft.) will have trouble holding this heat, while piles larger than 5 feet cubed (125 cu.ft.) don’t allow enough air to reach the microbes at the center. Those proportions are of importance only if your goal is a fast, hot compost.

**Time & Temperature**

All life on Earth needs a certain amount of water and air to sustain itself. The microbes in the compost pile are no different. They function best when the compost materials are about as moist as a wrung-out sponge, and are provided with many air passages. Extremes of sun or rain can adversely affect this moisture balance in your pile. If you use materials with a proper C:N ratio, provide a large amount of surface area and a big enough volume, and see that the moisture and aeration are adequate, you will have a hot, fast compost pile (hot enough to burn your hand!) and will probably want to use the turning unit discussed in the next section. If you just want to deal with your yard wastes in an inexpensive, easy, non-polluting way, the holding unit (also discussed on next page) will serve you well.

**What Can I Compost?**

Anything that was once alive can be composted. Yard wastes, such as fallen leaves, grass clippings, woods and the remains of garden plants, make excellent compost. Woody yard wastes can be chopped, shred, and run through a shredder for mulching and path-making. Used as a mulch or paths, the woody chips will eventually decompose. Small pieces also add texture to the compost pile.

Care must be taken when composting kitchen scraps. Compost them only by the methods outlined in this brochure. Meat, bones, dairy products and fatty foods (such as cheese, salad dressing, and leftover cooking oil) should be put in the garbage or In Clean Green programs where available.

**How Can I Use Compost?**

Compost can be used to enrich the flower and vegetable garden, to improve the soil around trees and shrubs, as a soil amendment for house plants and planter boxes and, when screened, as part of a seed-starting mix or lawn top-dressing. Before they decompose, chopped woody wastes can make excellent mulch or path material. After they decompose, these same woody wastes can be incorporated into garden soils to add texture.
Composting Yard Wastes

Holding Units
These simple containers for yard wastes are the least labor-intensive and least time-consuming way to compost.
Which wastes? Non-woody yard wastes are the most appropriate.
How? Place the holding unit where it is most convenient. As weeds without seeds, grass clippings, leaves and harvest remains from garden plants are collected, they can be dropped into the unit. Chopping or shredding wastes, alternating high-carbon and high-nitrogen materials, and keeping up good moisture and aeration will all speed the process.
Advantages & disadvantages For yard wastes this is the simplest method. The units can be portable, moving wherever needed in the garden. This method can take from 6 months to 2 years to compost organic materials, so you only need to be patient.
Variations Holding units can be made of circles of hardware cloth, old wooden pallets, or wood and wire. Sod can also be composted with or without the holding unit, by turning sections of sod over, making sure that there is adequate moisture, and covering the sod with black plastic.

Turning Units
This series of three or more bins allows wastes to be turned on a regular schedule. Turning units are most appropriate for gardeners with a large volume of yard waste and the desire to make high-quality compost.
Which wastes? Non-woody yard wastes are appropriate. Kitchen wastes without meat, bones, dairy products or fatty foods can be added to the center of a pile if it is turned weekly and reaches high temperatures.
How? Alternate the layering of high-carbon and high-nitrogen materials to approximately a 30:1 ratio. These should be moistened to the damp sponge stage. The pile temperature should be checked regularly: when the heat decreases substantially, turn the pile into the next bin. Dampen the materials if they are not moist, and add more high-nitrogen material if heating is not occurring. Then make a new pile in the original bin. Repeat the process each time the pile in the first bin cools. After two weeks in the third bin, the compost should be ready for garden use. See the Rødpen Guide to Composting in your library for more information on hot composting.
Advantages & disadvantages This method produces a high-quality compost in a short time utilizing a substantial input of labor.
Variations The unit can be built of wood/plastic, lumber, a combination of wood and wire, or concrete block. Another type of turning unit is a barrel compost, which tumbles the wastes for aeration.

The following troubleshooting chart is a guide to more efficient composting using a turning unit.

<table>
<thead>
<tr>
<th>SYMPTOM</th>
<th>PROBLEM</th>
<th>SOLUTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>The compost has a bad odor.</td>
<td>Not enough air or too much nitrogen.</td>
<td>Turn it and add brown dry, crispy material.</td>
</tr>
<tr>
<td>The center of the pile is dry.</td>
<td>Not enough water.</td>
<td>Misten materials while turning the pile.</td>
</tr>
<tr>
<td>The compost is damp &amp; warm in the middle, but nowhere else.</td>
<td>Too small.</td>
<td>Collect more materials and mix the old ingredients into the new pile.</td>
</tr>
<tr>
<td>The heap is damp and sweet-smelling but still will not heat up</td>
<td>Lack of nitrogens.</td>
<td>Mix in a nitrogen source like fresh grass clippings, fresh manure, bloodmeal or ammonium sulfate.</td>
</tr>
</tbody>
</table>

Composting Food Wastes

Mulching
Yard wastes can be used for weed control and water retention.
Which wastes? Woody yard wastes, leaves, and grass clippings.
How? You can simply spread leaves or grass clippings beneath plantings. For woody materials up to 1” in diameter, rent or purchase a chipper/shredder. Recomendations for organic mulch are: Woody material (3-4” deep) Dry grass clippings (1-2” deep) Keep material away from plant stems.
Advantages & disadvantages All yard wastes will work first as a mulch and then, as decomposition proceeds, as a soil enrichment. A disadvantage of mulching with woody yard wastes is that you may have to buy or rent power equipment.
Variations Use chipped materials for informal garden paths.

Soil Incorporation
Burying your organic wastes is the simplest method of composting.
Which wastes? Garden and yard wastes only. Burial of food wastes is illegal in some incorporated areas.
How? Everything should be buried at least 8 inches below the surface. Holes can be filled and covered, becoming usable garden spaces the following season.
Advantages & disadvantages This is a simple method, but because of the absence of air some nutrients will be lost. Rodents and dogs can become a problem with wastes buried less than 6 inches deep.
Variations Using a post hole digger, wastes can be incorporated into the soil near the drip-line of trees or shrubs and in small garden spaces.

Vermincomposting
Feeding earthworms in wooden bins is a good way to make high-quality compost from food scraps. Use Red Wigglers.
Which wastes? Kitchen scraps without meat, bones, dairy products or fatty foods.
How? Fill a bin with moistened bedding such as shredded newspaper for the worms. Rinse the burying of food wastes throughout the worm bin. Every 3-6 months the worm population should be divided and moved to fresh bedding. Refer to Worms Eat My Garbage by Mary Applehof (available at some library branches) for more information.
Advantages & disadvantages This is an efficient way to convert food wastes into a high-quality soil amendment for house plants, seedling transplants, or general garden use. The worms themselves are a useful product for fishing.
Variations A stationary outdoor bin can be used in all but the coldest months, or a portable indoor/ outdoor bin can be used year-round.
