## ACKNOWLEDGMENTS

---

Partial funding for these small grain and legume performance evaluations was provided by Idaho wheat, barley, and grain legume producers through cooperative research and extension grants from the Idaho Wheat Commission, the Idaho Barley Commission and the USA Dry Pea and Lentil Council. Support was also provided by the Idaho Agricultural Experiment Station and the University of Idaho Cooperative Extension System. Entry fees paid by private seed companies were also used to support the evaluations. This report represents the collective efforts of many individuals. The off-station nurseries were coordinated locally by County Educators with the Idaho Cooperative Extension System. Cooperator growers provided their time, land and other inputs for management of these trials and appreciation is expressed to them for their support. The University of Idaho Wheat Quality Laboratory at Aberdeen determined the protein content and kernel hardness of harvested wheat and barley samples. Appreciation is also expressed to the numerous support workers who assisted with trial establishment, maintenance, harvest, and grain processing. Finally, cereal breeders throughout the Northwest are recognized for their contributions since the nurseries would not be possible without their entries. The authors wish to thank all who have contributed to the success of this project.

## **Introduction**

This report summarizes the performance of winter wheat, spring wheat, winter barley, spring barley, winter pea, spring pea, lentil and chickpea varieties tested in extension variety trials conducted in northern Idaho during the 2014-2015 crop season. The variety trials were located in cooperators' fields at 9 test sites in Lewis, Nez Perce, Latah, Benewah and Boundary counties and on the University of Idaho Research and Extension Center farm in Moscow (Plant Science Farm).

Plant breeding and extension testing programs strive to increase yield potential through enhanced disease and insect resistance, winter hardiness, straw strength and other agronomic factors. In addition, varieties are developed for improved end-use quality and new markets. A more detailed description of variety development, cooperative extension testing and evaluation, and seed production programs is given in the University of Idaho publication CIS 976 titled, "Small Grain Variety Development and Adaptation in Idaho". Additional variety performance data for northern Idaho and the rest of the state can be viewed at the website [www.extension.uidaho.edu/cereals](http://www.extension.uidaho.edu/cereals). The northern Idaho Extension variety-testing program evaluates the relative performance of cereal and legume varieties grown in various northern Idaho environments under a range of commercial production conditions. Breeding lines that have shown promise through regional, public and private testing programs are evaluated along with leading commercially released varieties.

Increased field crop yield is the result of a combination of improved agronomic practices and advances in variety development. Trials reported in this publication help producers compare new varieties with widely grown varieties using field production practices common for their area. The provided information represents crop performance results from specific locations, production practices, and environmental conditions. Relative performance of varieties can change when tested under other environments and production practices. Evaluation of any variety included in these trials should not be construed as recommending any variety over varieties not included in the trials.

## **Cereal Test Procedures**

Seven winter cereal trials were planted in northern Idaho in the fall of 2014 and eight spring cereal trials were planted in the spring of 2015. For each crop, the seeding rate for all entries was a uniform number of seeds planted per square foot (spsf). These rates were determined by weighing 300 seeds of each cereal variety. Winter wheat and spring barley were planted at 23 spsf, spring wheat at 28 spsf, and winter barley at 21 spsf. Winter wheat, winter barley, spring wheat, and spring barley seeds were treated with Vibrance Extreme at 4 oz/100 lbs seed plus Dynashield at 0.26 oz/100 lbs seed. All plots were seeded 20 feet long. Plots in conventional tillage systems were seeded on 5-foot centers using a double-disc opener with 7 rows, 7-inches apart. Direct-seeded trials had five paired rows with 3-inch spacing and 10-inch from center to center of each opener. The direct-seed drill is equipped with Flexi-Coil Stealth openers that allow fertilizer to be banded below and between the paired rows. Typical cereal seeding depth varied from 0.75 to 1.5 inches depending on soil texture and moisture conditions. At each location, each variety entry was replicated four times in a randomized complete block design. After plants were well established, the beds were cut back to a plot size length of 15 feet with an application of glyphosate using a tractor-mounted, shielded sprayer between plots. For most trials conducted in collaboration with a grower cooperator, pesticides were applied by the grower while treating the remainder of the field surrounding the trial. Fertilizers and pesticides used in the trials are listed in Table 1 for the sites where the information was provided. Planting and harvesting operations by University of Idaho personnel were timed to approximately coincide with the cooperator's operations.

Prior to harvest, mature plant height was recorded, each plot was evaluated for lodging and plot length was measured to more accurately determine the harvestable area for each plot. Cereal plant height is the length of the plant from the soil surface to the tip of the head (awns excluded). For lodging, the affected area was scored from 0% to 100%, with 0% equal to no lodging and 100% being completely lodged. After harvest, each small grain entry at each location was evaluated for grain yield and test weight. Cereal test weight was reported in pounds per standard bushel. Cereal yields were reported in bushels per acre, using the standard 60 pounds per bushel conversion factor for wheat and 48 pounds per bushel for barley. Percentage grain plumps and thins were measured for barley. Plumpness is the percent of the sample that stayed on top of a 6/64-inch slotted screen after shaking. Thin percentage is the portion of the sample that went through a 5.5/64-inch slotted screen. Protein and kernel hardness were determined from a composite sample of four replications from each site for both winter and spring wheat. Wheat whole grain protein at 12% moisture was measured at the University of Idaho Wheat Quality Laboratory at Aberdeen using Near Infrared Spectrometry (NIRS) technology. Kernel hardness was also determined by NIRS. Values under 35 indicate soft wheat, and values above 35 indicate hard wheat.

### **Legume Test Procedures**

In the fall of 2014, two winter pea trials were established using a seeding rate of 10 spsf. In the spring of 2015, spring pea, lentil and chickpea trials were seeded near Craigmont, Genesee and Moscow. For each legume variety, 300 seeds were weighed and seeding rates calculated to give a uniform planting density of pea at 8 spsf, lentil at 8 spsf, and chickpea at 5 spsf. Spring pea and lentil seed were treated with an Apron (0.16 oz/cwt), Maxim (0.08 oz/cwt), Cruiser (0.5 oz/cwt), and molybdenum (0.1 oz/cwt) mix; and chickpea seed was treated Apron (0.2 oz/cwt), Maxim (0.08 oz/cwt), Mertect (2.04 oz/cwt), Cruiser (0.5 oz/cwt), and molybdenum (0.1 oz/cwt). All winter and spring legume plots were established in beds similar to the cereal trials; they were planted on 20-ft long beds that were cut back to 15-ft plots. Planting depths were between 1 and 2 inches for lentils and between 1.5 and 2.5 inches for pea and chickpea. Due to wider row spacing between plots, particularly for peas, chemical weed control was supplemented with hand weeding when necessary. Legumes were evaluated for vine length (pea) or plant height (lentil and chickpea), canopy height, seed yield, 100-seed weight and seed size (chickpea only). Lentil or chickpea plant height or pea vine lengths were measured from the soil surface to the end of the growing point on the main stem. Plant height and vine length measurements were recorded several weeks prior to harvest when plant tissue was green. Pea and lentil canopy height was measured from the soil surface to the average height of the canopy immediately prior to harvest. Seed yields were expressed in pounds per acre. Chickpea seed was sized by shaking 250 g of seed through screens. The screen sizes included 25/64", 22/64" and 20/64".

### **Statistical Interpretation**

Data in the tables is sorted by yield with the highest yielding entries listed first. The overall trial average is shown at the bottom of each table. The least significant difference (LSD) and the coefficient of variation (CV) are listed. The LSD is given at the 5 percent error level and aids in comparing varieties. If the measured values of any two varieties within a column differ by the LSD value or greater, they may be considered different with a confidence level of 95%. If the measured values are less than the LSD value, the differences may be due to random error rather than actual varietal differences. If no significant statistical differences were found among varieties, 'ns' (not significant) is shown for the LSD. The CV listed in the tables is given as a general measurement of the precision of each experiment. Lower CV percentage values indicate lower experimental variation and greater precision. A higher CV value indicates abnormal variation within the trial that could be due to external factors such as animal grazing, hail damage or other variable stress on the plants. CV values were not averaged across trials or years.

Variety choice should take into consideration as much performance data as possible with comparisons across years and locations. In addition to yield, other factors such as end use quality, disease and insect resistance, lodging tendency, maturity, plant height, winter hardiness, test weight, and any observations from grower experience can be used in deciding on which variety to plant. Due to seasonal variation, caution should be taken when looking at the results from a single growing season.

### **Growing Conditions and Factors Affecting Trial Results**

Fall cereal trials were planted from late September to mid-October. Winter wheat stands were well established at all locations. Fall temperatures were above normal. However, there were significant cold events in November and December with little to no snow cover. As a result, winter injury was observed at most locations for wheat, barley and pea. Despite the cold injury, all entries survived the winter with minimal to moderate reductions in plant density. Early winter precipitation was near normal, but the latter portion of winter was above normal and drier than normal. The spring and early summer were unusually dry, and unseasonably high temperatures were observed in late June and early July. Winter wheat yields were near normal with the exception of Lewiston which was above normal, benefiting from the warmer spring and timely rain, and Nezperce which was negatively impacted by dry, hot conditions. Spring crops were seeded in early to late April with the exception of the Craigmont legume trial which was seeded in early May. As a result of dry, hot conditions in 2015, there was significant injury to spring cereals and legumes. The yields for spring cereals and in some cases, the test weights are below normal. In addition, the heat resulted in the loss of blossoms, reducing the yield of spring and winter legumes at most locations.

Harvest for 2015 was early and was not influenced by weather events with the exception of a hailstorm that impacted the spring legumes in Genesee. No sprouting was observed in cereal crops. Due to widespread wildfires in northern Idaho during August of 2015, the lentil and chickpea trials at Craigmont were lost. The lentil trial at Moscow was also lost due to metribuzin injury following a series of significant rain events in late May.

Stripe-rust was rarely observed in winter or spring wheat due to a combination of unfavorable winter conditions and dry spring weather. With the exception of Bonners Ferry, environmental conditions were not conducive for disease development. Winter and spring plots were managed for stripe rust in Bonners Ferry, so very few symptoms were evident. Physiological leaf spot (PLS), an abiotic stress due to chloride deficiency, was observed in some wheat plots in 2015, but was not scored.

Average winter wheat yields in 2015 were 8 bu/A higher than the 3-year average for north Idaho. However, due to significant abiotic stresses mentioned above, the yield of spring crops was negatively impacted. The average spring wheat yield was 25 bu/A below the 3-year average and spring barley was 16 bu/A below the 3-year average. Likewise, the spring legume yield was well below the 3-year average for pea (1255 lb/A below), lentil (360 lb/A below) and chickpea (1009 lb/A below).

Specific trial locations and management practices used at each of the trial locations are listed in Table 1. A summary of released varieties tested during the 2014-2015 growing season is listed in Table 2. All data reported in Tables 3 to 42 have the yield for the individual location or north Idaho (multi-location) average yield list in order from highest to lowest yielding varieties.
