## ACKNOWLEDGMENTS

---

Partial funding for these small grain and legume performance evaluations was provided by Idaho wheat, barley, and grain legume producers through cooperative research and Extension grants from the Idaho Wheat Commission, the Idaho Barley Commission, and the USA Dry Pea and Lentil Council. Support was also provided by the Idaho Agricultural Experiment Station and the University of Idaho Cooperative Extension System. Entry fees paid by private seed companies were also used to support the evaluations. This report represents the collective efforts of many individuals. The off-station nurseries were coordinated locally by County Educators within the Idaho Cooperative Extension System. Cooperator growers provided their time, land, and other inputs for management of these trials and appreciation is expressed to them for their support. The University of Idaho Wheat Quality Laboratory at Aberdeen determined the protein content of harvested wheat and barley samples. Appreciation is also expressed to the numerous support workers who assisted with trial establishment, maintenance, harvest, and grain processing. Finally, cereal breeders throughout the Northwest are recognized for their contributions since the nurseries would not be possible without their entries. The authors wish to thank all who have contributed to the success of this project.

## **Introduction**

This report summarizes the performance of winter wheat, spring wheat, winter barley, spring barley, winter pea, spring pea, lentil, and chickpea varieties tested in Extension variety trials conducted in northern Idaho during the 2017–2018 crop season. The variety trials were located in cooperators' fields at nine test sites in Idaho, Lewis, Nez Perce, Latah, Benewah, and Boundary Counties and on the University of Idaho Research and Extension Center farm in Moscow (Plant Sciences Farm). Specific trial locations and management practices used at each of the trial locations are listed in Table 1.

Plant breeding and Extension testing programs strive to increase yield potential through enhanced disease and insect resistance, winter hardiness, straw strength, and other agronomic factors. In addition, varieties are developed for improved end-use quality and new markets. Additional variety performance data for northern Idaho and the rest of the state can be viewed at the website [www.uidaho.edu/extension/cereals](http://www.uidaho.edu/extension/cereals). The northern Idaho Extension variety-testing program evaluates the relative performance of cereal and legume varieties grown in various northern Idaho environments under a range of commercial production conditions. Breeding lines that have shown promise through regional, public, and private testing programs are evaluated along with leading commercially released varieties.

Increased field crop yield is the result of a combination of improved agronomic practices and advances in variety development. Trials reported in this publication help producers compare new varieties with widely grown varieties using field production practices common for their area. The provided information represents crop performance results from specific locations, production practices, and environmental conditions. Relative performance of varieties can change when tested under other environments and production practices. Evaluation of any variety included in these trials should not be construed as recommending any variety over varieties not included in the trials.

## **Cereal Test Procedures**

Seven winter cereal trials were planted in northern Idaho in the fall of 2017 and eight spring cereal trials were planted in the spring of 2018. For each crop, the seeding rate for all entries was a uniform number of seeds planted per square foot (spsf). These rates were determined by weighing 1,000 seeds of each cereal variety. Winter wheat and spring barley were planted at 23 spsf, spring wheat at 28 spsf, and winter barley at 21 spsf. Winter wheat, winter barley, spring wheat, and spring barley seeds were treated with Vibrance Extreme at 2.8 oz/100 lbs seed plus Sharda 1.0 oz/100 lbs seed. All plots were seeded 20 ft long. Plots in conventional tillage systems were seeded on 5 ft centers using a double-disc opener with 7 rows, 7 in apart. Direct-seeded trials had five paired rows with 3 in spacing and 10 in from center to center of each opener. The direct-seed drill is equipped with Flexi-Coil Stealth openers that allow fertilizer to be banded below and between the paired rows. Typical cereal seeding depth varied from 0.75 to 1.5 in depending on soil texture and moisture conditions. At each location, each variety entry was replicated four times in a randomized complete block design. After plants were well established, the beds were cut back to a plot size length of 15 ft with an application of Glyphosate herbicide using a tractor-mounted, shielded sprayer between plots. For most trials conducted in collaboration with a grower cooperator, pesticides were applied by the grower while treating the remainder of the field surrounding the trial. Fertilizers and pesticides used in the trials are listed in Table 1 for the sites where the information was provided. Planting and harvesting operations by University of Idaho personnel were timed to approximately coincide with the cooperator's operations.

Prior to harvest, mature plant height was recorded, each plot was evaluated for lodging, and plot length was measured to more accurately determine the harvestable area for each plot. Cereal plant height is the length of the plant from the soil surface to the tip of the head (awns excluded). For lodging, the affected area was scored from 0% to 100%, with 0% equal to no lodging and 100% being completely lodged. After harvest, each small grain entry at each location was evaluated for grain yield and test weight. Cereal test weight was reported in pounds per standard bushel. Cereal yields were reported in bushels per acre, using a standard

60 lbs/bu conversion factor for wheat and 48 lbs/bu for barley. Percentage grain plumps and thins were measured for barley. Plumpness is the percent of the sample that stayed on top of a 5.5/64 in slotted screen after shaking. Thin percentage is the portion of the sample that went through a 5.5/64 in slotted screen. Wheat whole grain protein at 12% moisture was measured at the University of Idaho Wheat Quality Laboratory at Aberdeen using Near Infrared Spectrometry (NIRS) technology. For winter and spring wheat samples, all four replications were tested for protein, but the barley samples consisted of a single composite sample for each variety at each location.

### **Legume Test Procedures**

In the fall of 2017, two winter pea trials were established using a seeding rate of 10 spsf. In the spring of 2018, spring pea, lentil, and chickpea trials were seeded near Craigmont, Genesee, and Moscow. For each legume variety, 1,000 seeds were weighed and seeding rates calculated to give a uniform planting density of pea at 8 spsf, lentil at 8 spsf, and chickpea at 5 spsf. Spring pea and lentil seed were treated with an Apron (0.16 oz/cwt), Maxim (0.08 oz/cwt), Cruiser (0.5 oz/cwt), and molybdenum (0.1 oz/cwt) mix; and chickpea seed was treated with Apron (0.2 oz/cwt), Maxim (0.08 oz/cwt), Mertect (2.04 oz/cwt), Cruiser (0.5 oz/cwt), and molybdenum (0.1 oz/cwt). All winter and spring legume plots were established in beds similar to the cereal trials; they were planted on 20 ft long beds that were cut back to 15 ft plots. Planting depths were between 1 and 1.5 in for lentils and between 1.5 and 2.5 in for pea and chickpea. Due to wider row spacing between plots, particularly for peas, chemical weed control was supplemented with hand weeding when necessary. Legumes were evaluated for vine length (pea) or plant height (lentil and chickpea), canopy height at harvest, seed yield, 100-seed weight and seed size (chickpea only). Lentil or chickpea plant height or pea vine lengths were measured from the soil surface to the end of the growing point on the main stem. Plant height and vine length measurements were recorded several weeks prior to harvest when plant tissue was green. Pea and lentil canopy height was measured from the soil surface to the average height of the canopy immediately prior to harvest. Seed yields were expressed in pounds per acre. Chickpea seed was sized by shaking 250 g of seed through screens. The screen sizes included 25/64", 22/64", and 20/64".

### **Statistical Interpretation**

Data in the tables are sorted by yield with the highest-yielding entries listed first. The overall trial average is shown at the bottom of each table. The least significant difference (LSD) and the coefficient of variation (CV) are listed. The LSD is given at the 5% error level and aids in comparing varieties. If the measured values of any two varieties within a column differ by the LSD value or greater, they may be considered different with a confidence level of 95%. If the measured values are less than the LSD value, the differences may be due to random error rather than actual varietal differences. If no significant statistical differences were found among varieties, "ns" (not significant) is shown for the LSD. The CV listed in the tables is given as a general measurement of the precision of each experiment. Lower CV percentage values indicate lower experimental variation and greater precision. A higher CV value indicates abnormal variation within the trial that could be due to external factors such as animal grazing, hail damage, or other variable stress on the plants. CV values were not averaged across trials or years.

Variety choice should take into consideration as much performance data as possible with comparisons across years and locations. In addition to yield, other factors such as end use quality, disease and insect resistance, lodging tendency, maturity, plant height, winter hardiness, test weight, and any observations from grower experience can be used in deciding on which variety to plant. Due to seasonal variation, caution should be taken when looking at the results from a single growing season. A summary of released varieties tested during the 2017–2018 growing season is listed in Table 2.

## 2017–2018 Growing Conditions and Factors Affecting Trial Results

### *Fall crop conditions:*

Fall cereal trials were planted from late September to mid-October. There were rain events prior to seeding and during October. As a result, there was good soil moisture and winter crops established well at all locations. The average temperatures were near normal for much of the year, but February and March were warmer than normal which allowed for greater early season growth (Figure 1A). There was little to no evidence of winter injury at any location. The precipitation between September 2017 and June 2018 was 4.4 in above normal at Moscow (Figure 1B). The greater winter and spring precipitation appears to have resulted in some nitrogen leaching and reduced seed protein content, particularly in the winter cereals.

### *Spring crop conditions:*

Spring precipitation was well above normal in northern Idaho, particularly during April (Figure 1B). This resulted in delayed seeding for all spring trials. Most locations were seeded before the end of April, but seeding was not completed until the middle of May. Conditions in May and June were near normal, but there was virtually no precipitation in July and August. This lack of late-season precipitation resulted in lower test weights in spring cereals, particularly for the spring wheat. Conditions were dry during the harvest season and there was no evidence of sprout in any of the wheat or barley plots.

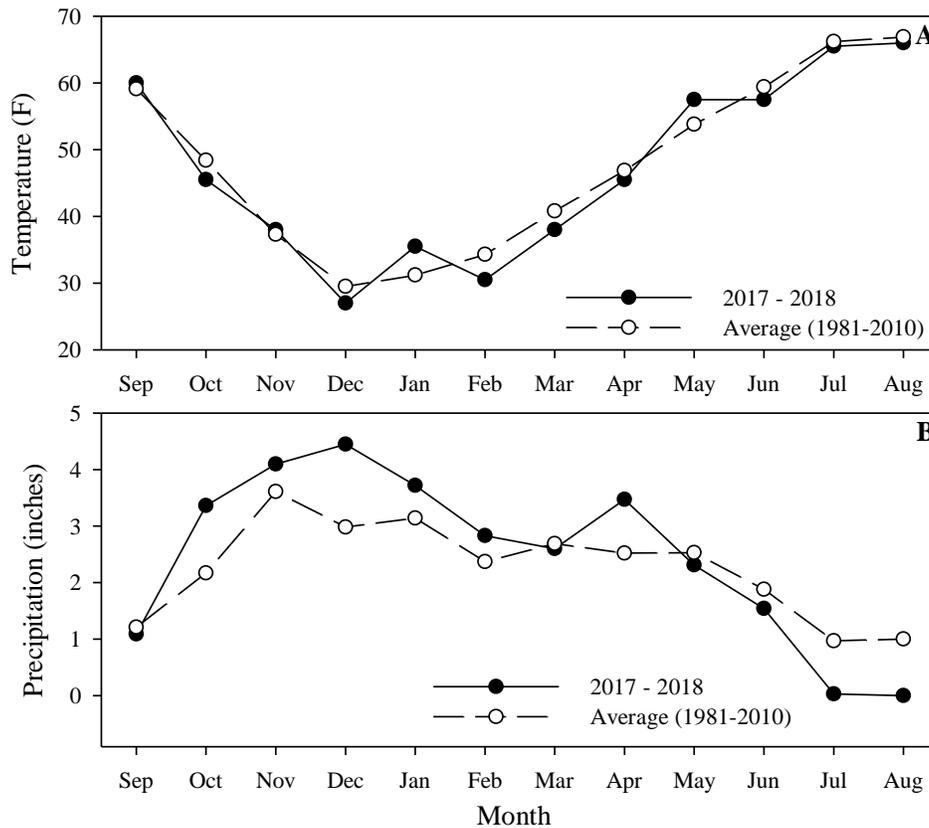

Figure 1. Mean monthly temperature (A) and precipitation (B) for the 2017–2018 growing season at the Parker Plant Sciences Farm east of Moscow compared to thirty-year average.

#### *Diseases and pests:*

Stripe rust (*Puccinia striiformis* f. sp. *tritici*) on wheat is commonly observed in northern Idaho. Conditions were conducive for development of stripe rust in the spring of 2018. Stripe rust pressure was moderate and timely fungicide applications and disease resistance in the wheat varieties or lines resulted in very little stripe rust development in the plots. As a result, no notes were collected on this disease. Cephalosporium stripe (*Cephalosporium graminearum*) was observed at some locations, but there was not substantial damage caused by this pathogen. Earlier seeding and establishment of winter wheat created conditions that were more conducive for infection. While not a disease, physiological leaf spot was observed at several winter wheat locations. Not all varieties will display symptoms of physiological leaf spot and there are mixed results as to whether this disorder will result in yield reduction. The wet, cool spring conditions seem to exacerbate symptoms. In general, plant diseases and disorders did not have a substantial role in crop performance in 2018.

Two insect pests were observed frequently in the 2018 trials. The first was pea weevil (*Bruchus pisorum*), which was observed in all fall and spring sown plots. Despite managing for pea weevil with insecticide application, damaged seed was observed at harvest and resulted in lower 100-seed weights. This pest can be adequately managed by application of insecticide soon after first bloom and repeating as necessary. This becomes somewhat problematic in a variety trial when not all varieties bloom at the same time.

The second insect pest was Hessian fly (*Mayetiola destructor*). There was evidence of this pest being present in the Bonners Ferry and Craigmont spring wheat plots. While not common in winter wheat, it also was observed in select winter wheat entries in Bonners Ferry as a low frequency pest. Many of the spring wheat varieties and lines included in the northern Idaho variety trials are resistant to Hessian fly, but those that lacked resistance were impacted by this insect. The severity of Hessian fly varies from year to year, but is best managed by seeding resistant spring wheat varieties.

### **Summary of 2017–2018 Results**

Data is reported for all trials and locations that were seeded in the fall of 2017 and spring of 2018. While many of the plots were impacted by weather events, diseases, or pests as outlined above, there was acceptable data produced for each of the trials. As noted, in some cases not all varieties or entries are included at all locations.

A summary of selected agronomic characteristics for winter wheat, spring wheat, spring barley, and spring legumes is shown in Tables 3 and 4. Winter wheat yields in 2018 were 18 bu/A above the ten-year average. Winter wheat test weight in 2018 was the fourth highest for the past ten years at an average of 60.8 lb/bu. Due to delayed seeding and dry summer conditions, the yield for spring wheat was 5 bu/A below the ten-year average while the spring barley yield was 6 bu/A below average. Test weight for spring wheat were 1.1 lb/bu below the ten-year average while test weight for spring barley was 1.2 lb/bu above average.

While seeding was delayed for the spring legumes, the yields were near the ten-year average for each crop. The 2018 spring pea yield was equal to or just above the ten-year average with 2115 lb/A, but as alluded to earlier, the average 100-seed count was 1 g below average. Lentil yield was 64 lb/A below the ten-year average at 1076 lb/A, with a 100-seed weight just below the average. Likewise, chickpea was just below average at 1898 lb/A. However, the 100-seed weight and proportion of seed larger than 22/64” was much lower than average and the lowest since these data started being collected in 2014.

Specific yield data for all northern Idaho trials along with multilocation summaries are listed in Tables 5–54. Varieties or breeding lines are listed in order from highest yielding to lowest yielding in each table.

\*Variety or selection yields in bold were statistically equal to the top yielding variety. Multilocation averages were not calculated for Rebelde, Mandala, and Metropolis because these entries were not included at all locations. LWW14-73915 could not be included in the northern Idaho average yield due to wildlife herbivory at Bonnors Ferry.

\*\*Irv was previously tested as OR2110679 and WB4311 was XA4104.

\*Buck is a hulless variety. The two-row hulless selection 05ARS748-270 was included at this site, but no data is available due to poor establishment and significant wildlife damage.

\*\*Variety or selection yields in bold were statistically equal to the top yielding variety. Yield is not reported for 07ARS518-13 and LCS Calypso as these two entries were significantly damaged by wildlife.
